

COMS W4733: Computational Aspects of Robotics

Lecture 6: Inverse Differential Kinematics

Instructor: Tony Dear

Review: Differential Kinematics

- Joint variables $\mathbf{q} = (q_1, \dots, q_n)^T \in$ **configuration space**
- End effector pose $\mathbf{x}_e \in$ **operational space**
- Differential kinematics: *Linear mapping* from joint velocities $\dot{\mathbf{q}}$ to end effector velocities $\dot{\mathbf{x}}_e$
- **Jacobian**: Configuration-dependent matrix $\mathbf{J}(\mathbf{q})$
- 6 rows, one for each $\dot{\mathbf{x}}_e$ component (in 3D)
 - $\dot{\mathbf{x}}_e = (\dot{\mathbf{p}}_e^T, \dot{\boldsymbol{\omega}}_e^T)^T = (\dot{x}, \dot{y}, \dot{z}, \omega_x, \omega_y, \omega_z)^T$
- n columns, one for each joint

$$\dot{\mathbf{x}}_e = \mathbf{J}(\mathbf{q})\dot{\mathbf{q}}$$

Review: The Jacobian

$$\mathbf{v}_e = \begin{pmatrix} \dot{\mathbf{p}}_e \\ \boldsymbol{\omega}_e \end{pmatrix} = \begin{pmatrix} \mathbf{J}_P(\mathbf{q}) \\ \mathbf{J}_O(\mathbf{q}) \end{pmatrix} \dot{\mathbf{q}} = \mathbf{J}(\mathbf{q}) \dot{\mathbf{q}}$$

- Linear velocity Jacobian

$$\mathbf{J}_P(\mathbf{q}) = \begin{pmatrix} \frac{\partial p_{e,x}}{\partial q_1} & \dots & \frac{\partial p_{e,x}}{\partial q_n} \\ \frac{\partial p_{e,y}}{\partial q_1} & \dots & \frac{\partial p_{e,y}}{\partial q_n} \\ \frac{\partial p_{e,z}}{\partial q_1} & \dots & \frac{\partial p_{e,z}}{\partial q_n} \end{pmatrix}$$

Or column by column:

$$[\mathbf{J}_{Pi}] = \begin{cases} [\mathbf{z}_{i-1}^0] & \text{prismatic} \\ [\mathbf{z}_{i-1}^0 \times (\mathbf{p}_e - \mathbf{p}_{i-1})] & \text{revolute} \end{cases}$$

- Angular velocity Jacobian

$$[\mathbf{J}_{Oi}] = \begin{cases} [\mathbf{0}] & \text{prismatic} \\ [\mathbf{z}_{i-1}^0] & \text{revolute} \end{cases}$$

The Inverse Problem

- Inverse position kinematics: Nonlinear, difficult to find closed-form solutions; even numerical solutions often involve some optimization or gradient descent
- Differential mapping between velocities is linear—can we simply invert it?
 - Solving for joint velocities will also help with joint configurations (next lecture)!
- If the Jacobian is square and nonsingular, then the problem is easy: $\dot{\mathbf{q}} = \mathbf{J}^{-1}(\mathbf{q})\mathbf{v}_d$
- Number of joints must equal number of *desired workspace velocities* \mathbf{v}_d

Square Jacobians

- RR arm is 3×2 . Not square!
- We can only specify two desired velocities:

$$\dot{\mathbf{q}} = \begin{pmatrix} -l_1 s_1 - l_2 s_{12} & -l_2 s_{12} \\ l_1 c_1 + l_2 c_{12} & l_2 c_{12} \end{pmatrix}^{-1} \begin{pmatrix} \dot{x}_d \\ \dot{y}_d \end{pmatrix}$$

$$\dot{\mathbf{q}} = \begin{pmatrix} -l_1 s_1 - l_2 s_{12} & -l_2 s_{12} \\ 1 & 1 \end{pmatrix}^{-1} \begin{pmatrix} \dot{x}_d \\ \omega_{z,d} \end{pmatrix}$$

$$\mathbf{J}_{RR} = \begin{pmatrix} -l_1 s_1 - l_2 s_{12} & -l_2 s_{12} \\ l_1 c_1 + l_2 c_{12} & l_2 c_{12} \\ 1 & 1 \end{pmatrix}$$

- RRR arm is 3×3 . We can fully specify $(\dot{x}, \dot{y}, \omega_z)^T$ and invert \mathbf{J}

$$\dot{\mathbf{q}} = \mathbf{J}_{RRR}^{-1} \begin{pmatrix} \dot{x}_d \\ \dot{y}_d \\ \omega_{z,d} \end{pmatrix}$$

$$\mathbf{J}_{RRR} = \begin{pmatrix} -l_1 s_1 - l_2 s_{12} - l_3 s_{123} & -l_2 s_{12} - l_3 s_{123} & -l_3 s_{123} \\ l_1 c_1 + l_2 c_{12} + l_3 c_{123} & l_2 c_{12} + l_3 c_{123} & l_3 c_{123} \\ 1 & 1 & 1 \end{pmatrix}$$

Underconstrained Manipulators

- *Underconstrained / redundant* manipulator: Fewer specifications than DOFs
- Occurs when more than 3 DOFs in 2D or more than 6 DOFs in 3D
- Also when fewer pose velocities are required

- Jacobian: Fewer rows (r) than columns (n)—more than one solution to IDK

$$J\dot{q} = v_d \iff \dot{q} = J^T(JJ^T)^{-1}v_d \iff \dot{q} = W^{-1}J^T(JW^{-1}J^T)^{-1}v_d$$

- JJ^T is $r \times r$ and square—invertible!

- Non-singular iff J is non-singular
- W is an invertible matrix as well

$$\begin{pmatrix} \dot{x}_d \\ \dot{y}_d \end{pmatrix} = J_{RRR}\dot{q}$$

Underconstrained Manipulators

$$\dot{\mathbf{q}} = \mathbf{W}^{-1} \mathbf{J}^T (\mathbf{J} \mathbf{W}^{-1} \mathbf{J}^T)^{-1} \mathbf{v}_d$$

- Suppose \mathbf{W} is symmetric and positive-definite
- Then the above minimizes a cost function in joint velocities: $g(\dot{\mathbf{q}}) = \frac{1}{2} \dot{\mathbf{q}}^T \mathbf{W} \dot{\mathbf{q}}$
- Ex: Suppose $(q_1, q_2, q_3)^T = (60^\circ, -30^\circ, 15^\circ)^T$ and $\mathbf{v}_d = (\dot{x}_d, \dot{y}_d)^T = (1, 1)^T$ m/s

$$\mathbf{J}_{RRR} = \begin{pmatrix} -2.07 & -1.21 & -0.71 \\ 2.07 & 1.57 & 0.71 \end{pmatrix}$$

$$\mathbf{W} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}$$

$$\dot{\mathbf{q}} = \begin{pmatrix} -3.59 \\ 5.56 \\ -0.41 \end{pmatrix}$$

Solution tries to have smaller $|\dot{\theta}_3|$

$$\mathbf{W} = \begin{pmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$\dot{\mathbf{q}} = \begin{pmatrix} -2.76 \\ 5.56 \\ -2.84 \end{pmatrix}$$

Solution tries to have smaller $|\dot{\theta}_1|$

Right Pseudo-inverse

$$\dot{\mathbf{q}} = \mathbf{W}^{-1} \mathbf{J}^T (\mathbf{J} \mathbf{W}^{-1} \mathbf{J}^T)^{-1} \mathbf{v}_d$$

- For the special case $\mathbf{W} = \mathbf{I}$, all joint velocities are equally weighted

$$\dot{\mathbf{q}} = \mathbf{J}^T (\mathbf{J} \mathbf{J}^T)^{-1} \mathbf{v}_d = \mathbf{J}_r^+ \mathbf{v}_d$$

- Right pseudo-inverse* of \mathbf{J} defined s.t. $\mathbf{J} \mathbf{J}_r^+ = \mathbf{I}$

- Moore-Penrose conditions:**
 - $\mathbf{J}^+ \mathbf{J} \mathbf{J}^+ = \mathbf{J}^+$
 - $\mathbf{J} \mathbf{J}^+ \mathbf{J} = \mathbf{J}$
 - $(\mathbf{J} \mathbf{J}^+)^T = \mathbf{J} \mathbf{J}^+$
 - $(\mathbf{J}^+ \mathbf{J})^T = \mathbf{J}^+ \mathbf{J}$
- Other useful properties:
 - $(\mathbf{J}^+)^+ = \mathbf{J}$
 - $(\mathbf{J}^+)^T = (\mathbf{J}^T)^+$

Jacobian Null Space

- For an underconstrained manipulator, the Jacobian maps from a higher-dimensional input (n joint DOF columns) to a lower-dimensional output (r desired velocity rows)
- A non-singular matrix has rank r (if $r \leq n$) and *null space* dimension $n - r$
 - Subspace of joint velocities $\dot{\mathbf{q}}$ that map to **zero** end effector velocities
- $(\mathbf{I} - \mathbf{J}_r^+ \mathbf{J})\dot{\mathbf{q}}_0$ lives in the null space of \mathbf{J} because

$$\mathbf{J}(\mathbf{I} - \mathbf{J}_r^+ \mathbf{J})\dot{\mathbf{q}}_0 = (\mathbf{J} - \mathbf{J}\mathbf{J}_r^+ \mathbf{J})\dot{\mathbf{q}}_0 = (\mathbf{J} - \mathbf{J})\dot{\mathbf{q}}_0 = \mathbf{0}$$

- Therefore we can add $(\mathbf{I} - \mathbf{J}_r^+ \mathbf{J})\dot{\mathbf{q}}_0$ to any joint velocity solution without changing the desired end effector velocity

Homogeneous Solution

$$\dot{\mathbf{q}} = \mathbf{J}_r^+ \mathbf{v}_d + (\mathbf{I} - \mathbf{J}_r^+ \mathbf{J}) \dot{\mathbf{q}}_0$$

- The second term is the **homogeneous solution** and minimizes a new cost function

$$g'(\dot{\mathbf{q}}) = \frac{1}{2}(\dot{\mathbf{q}} - \dot{\mathbf{q}}_0)^T(\dot{\mathbf{q}} - \dot{\mathbf{q}}_0)$$

- Simultaneously solve the IDK problem while returning a $\dot{\mathbf{q}}$ close to a specified $\dot{\mathbf{q}}_0$
- One idea: Choose $\dot{\mathbf{q}}_0$ to maximize secondary objective function: $\dot{\mathbf{q}}_0 = k_0 \left(\frac{\partial w(\mathbf{q})}{\partial \mathbf{q}} \right)^T$

- Ex: Distance from joint limits $\sum_{i=1}^n \left(\frac{q_i - \bar{q}_i}{q_{iM} - q_{im}} \right)^2$ Joint i ranges from q_{im} to q_{iM} ;
middle value is \bar{q}_i

- Ex: Distance from obstacle

Overconstrained Manipulators

- *Overconstrained* manipulator: More specifications (rows) than DOFs (columns)
- Not enough DOFs to find exact joint velocity solutions
- Jacobian: Fewer columns than rows ($n < r$)
- Right pseudo-inverse undefined since $J^T J$ has rank $n < r$
- Instead, we define the *left pseudo-inverse*: $J_l^+ = (J^T J)^{-1} J^T$, s.t. $J_l^+ J = I$
- $J^T J$ is $n \times n$ and therefore full rank and invertible
- J_l^+ also satisfies Moore-Penrose conditions

Left Pseudo-inverse

$$\dot{\mathbf{q}} = (\mathbf{J}^T \mathbf{J})^{-1} \mathbf{J}^T \mathbf{v}_d = \mathbf{J}_l^+ \mathbf{v}_d$$

- Although we can't get exact solutions, the left pseudo-inverse tries to minimize the resulting error: $g(\dot{\mathbf{q}}, \mathbf{v}_d) = \frac{1}{2}(\mathbf{v}_d - \mathbf{J}\dot{\mathbf{q}})^T(\mathbf{v}_d - \mathbf{J}\dot{\mathbf{q}})$

- Ex: Suppose $(q_1, q_2)^T = (30^\circ, 30^\circ)^T$ and $\mathbf{v}_d = (\dot{x}_d, \dot{y}_d, \omega_d)^T = (1, 1, 1)^T$

$$\mathbf{J}_{RR} = \begin{pmatrix} -1.366 & -0.866 \\ 1.366 & 0.5 \\ 1 & 1 \end{pmatrix} \Rightarrow \dot{\mathbf{q}} = \begin{pmatrix} 0.146 \\ 0.107 \end{pmatrix} \Rightarrow \dot{\mathbf{x}} = \begin{pmatrix} -0.293 \\ 0.254 \\ 0.254 \end{pmatrix}$$

- What if $\mathbf{v}_d = (-2, 2, 2)^T$? $\dot{\mathbf{q}} = \begin{pmatrix} 1.093 \\ 0.8 \end{pmatrix} \Rightarrow \dot{\mathbf{x}} = \begin{pmatrix} -2.186 \\ 1.893 \\ 1.893 \end{pmatrix}$

Singularities

- Recall: Singularities occur at configurations at workspace boundaries or when the robot loses DOFs
- Square Jacobians lose rank and cannot be inverted
- $\det(\mathbf{J})$ cannot be computed for non-square Jacobians
- If underconstrained ($r < n$), check $\det(\mathbf{J}\mathbf{J}^T)$
 - Both \mathbf{J} and $\mathbf{J}\mathbf{J}^T$ should have full rank r ; $\mathbf{J}\mathbf{J}^T$ is $r \times r$
- If overconstrained ($n < r$), check $\det(\mathbf{J}^T\mathbf{J})$
 - Both \mathbf{J} and $\mathbf{J}^T\mathbf{J}$ should have full rank n ; $\mathbf{J}^T\mathbf{J}$ is $n \times n$

Singular Value Decomposition

- We cannot compute either pseudo-inverse when the Jacobian is not full-rank
- Can we somehow ignore the “singular parts” and operate on the rest of the matrix?

- Recall the SVD of a matrix: $J = U\Sigma V^T$

- U is $r \times r$, orthonormal (eigenvectors of JJ^T)
- V is $n \times n$, orthonormal (eigenvectors of $J^T J$)
- Σ is $r \times n$, semi-diagonal matrix of *singular values*

$$\Sigma = \begin{pmatrix} D & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} \quad D = \begin{pmatrix} \sigma_1 & 0 & \cdots & 0 \\ 0 & \sigma_2 & \ddots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_{\text{rank}(J)} \end{pmatrix}$$

$r < n$:

$$\Sigma = \begin{pmatrix} \sigma_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & \sigma_2 & \ddots & 0 & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_r & \cdots & 0 \end{pmatrix}$$

$n < r$:

$$\Sigma = \begin{pmatrix} \sigma_1 & 0 & \cdots & 0 \\ 0 & \sigma_2 & \ddots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \ddots & \sigma_n \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix}$$

Inverting the SVD

- When we compute (either) pseudo-inverse, we're computing the following:

$$J^+ = V\Sigma^+U^T$$

- $r < n$:
$$\Sigma = \begin{pmatrix} \sigma_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & \sigma_2 & & 0 & & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_r & \cdots & 0 \end{pmatrix} \quad \Rightarrow \quad \Sigma^+ = \begin{pmatrix} 1/\sigma_1 & 0 & \cdots & 0 \\ 0 & 1/\sigma_2 & & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \ddots & 1/\sigma_r \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix}$$

- $n < r$:
$$\Sigma = \begin{pmatrix} \sigma_1 & 0 & \cdots & 0 \\ 0 & \sigma_2 & & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \ddots & \sigma_n \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} \quad \Rightarrow \quad \Sigma^+ = \begin{pmatrix} 1/\sigma_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & 1/\sigma_2 & & 0 & & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1/\sigma_n & \cdots & 0 \end{pmatrix}$$

Singular Pseudo-inverse

- When the Jacobian is full-rank, the singular values matrix takes either of the two forms

$$\Sigma = \begin{pmatrix} D & \mathbf{0} \end{pmatrix} \quad \Sigma = \begin{pmatrix} D \\ \mathbf{0} \end{pmatrix}$$

- If the Jacobian becomes singular, one or more singular values become zero and the matrix takes the full form $\Sigma = \begin{pmatrix} D & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix}$

- The (pseudo-)inverse attempts to invert the zeros along the diagonal and fails!
- We can manually compute an inverse of J by deliberately skipping those zero values:

$$J^+ = V \Sigma^+ U^T \quad \Sigma^+ = \begin{pmatrix} D^+ & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} \quad D^+ = \begin{pmatrix} 1/\sigma_1 & 0 & \cdots & 0 \\ 0 & 1/\sigma_2 & \ddots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1/\sigma_{\text{rank}(J)} \end{pmatrix}$$

Singular Inverse Example

- RR arm at configuration $\mathbf{q} = (30^\circ, 0^\circ)^T$ is singular for (\dot{x}, \dot{y})

$$J_{RR} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T = \begin{pmatrix} -0.5 & \sqrt{3}/2 \\ \sqrt{3}/2 & 0.5 \end{pmatrix} \begin{pmatrix} 2.236 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0.894 & 0.447 \\ -0.447 & 0.894 \end{pmatrix}$$

$$J_{RR}^+ = \mathbf{V}\mathbf{\Sigma}^+ \mathbf{U}^T = \begin{pmatrix} 0.894 & -0.447 \\ 0.447 & 0.894 \end{pmatrix} \begin{pmatrix} 0.447 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} -0.5 & \sqrt{3}/2 \\ \sqrt{3}/2 & 0.5 \end{pmatrix} \\ = \begin{pmatrix} -0.2 & 0.346 \\ -0.1 & 0.173 \end{pmatrix}$$

Ex: $(\dot{x}, \dot{y}) = (-1, \sqrt{3})$

$$\dot{\mathbf{q}} = \begin{pmatrix} \dot{\theta}_1 \\ \dot{\theta}_2 \end{pmatrix} = J_{RR}^+ \begin{pmatrix} -1 \\ \sqrt{3} \end{pmatrix} = \begin{pmatrix} 0.8 \\ 0.4 \end{pmatrix}$$

Check: $\begin{pmatrix} -1 \\ \sqrt{3} \end{pmatrix} = J_{RR} \begin{pmatrix} 0.8 \\ 0.4 \end{pmatrix}$

$$J_{RR} = \begin{pmatrix} -l_1 s_1 - l_2 s_{12} & -l_2 s_{12} \\ l_1 c_1 + l_2 c_{12} & l_2 c_{12} \end{pmatrix} \\ = \begin{pmatrix} -1 & -0.5 \\ \sqrt{3} & \sqrt{3}/2 \end{pmatrix}$$

Summary

- IDK: Solve for joint velocities to achieve desired workspace velocities
- When Jacobian is non-singular and square, a simple inverse is sufficient
- If Jacobian is underconstrained ($r < n$), use the right pseudo-inverse
 - Minimizes joint velocities, can also weight individual joints
 - Homogeneous solution characterized by null space, since there are infinite solutions
- Otherwise there may be no exact solutions!
- If Jacobian is overconstrained ($n < r$), use the left pseudo-inverse
- If Jacobian is singular, can use SVD to manually compute an inverse
